Marking Scheme of Model Test Paper

Class 10th

Subject-Construction

Q No.	Answer	Marks
1.	Laying of Bricks in Walls	5
	Laying of bricks in a wall is done in the following two steps:	
	(a) Laying of bricks in the foundation that is up to the plinth level.	
	(b) Laying of bricks in the wall above the plinth level.	
	Laying of Bricks in the Foundation upto the	
	Plinth Level	
	The steps to lay bricks is as follows:	
	(i) Spreading mortar on a concrete bed: about 2 cm thick layer of prepared mortar is first spread on top of the concrete bed in the area to be occupied by the corners.	
	(ii) Constructing corners: after spreading the mortar, the extreme corners are constructed in two coursesafter leaving the required concrete offset on eachside. The surfaces of these extreme corners are made in vertical direction.	
	(iii) Laying the first course: first, two strings are stretched at the upper level between the extreme corners to mark the external and internal edges and to lay the bricks in line and level with the corner bricks of this course. Then the bricks are laid on the layer of the mortar between these	
	strings, till the first course is completed.	
	English Bond consists of an alternate course of headers and stretchers .	
	Queen closer, that is, half of the brick cut lengthwise, shall be introduced after the first header to break the vertical joint.	
	• Flemish Bond is an arrangement of bonding brickwork. Each course consists of alternate headers and stretchers. The headers of each course	
	are centred over the stretcher in the course below.For breaking of vertical joints in successive courses, closers are inserted in alternate courses next to quoin (a cornerstone) headers.	
2	Shuttering for the column	5
	(a) The side yokes are two each.	
	(b) They are suitably spaced along the height of the column	
	Shuttering for Beam and Slab Floor	
	(a) The ends of the battens are supported on the ledger, which is	
	fixed to the cleats throughout the length	
	Shuttering for Stairs	
	(a) The riser planks are fixed after reinforcement has been fixed in position	
	(b) A cut string made of a 5 cm plank carriesthe outer end of the risers. Or	

	 Slabs and beams are usually constructed together by laying concrete in the formwork. The formwork consists of rows of vertical posts, which carry wooden beams on top. Wooden or steel planks are placed on top of the horizontal beams. At different heights, the vertical posts are suitably supported by lateral posts from the sides. The bottom of the vertical posts rests on tapered wooden wedges and flat steel plates. For constructing a formwork for a beam, the formwork is supported by tapering blocks from the sides, bad beam from the bottom and the beam is supported by wooden blocks and struts on the vertical posts. Some important points are given below. (a) The slab is continuous over a number of beams. (b) The slab is supported on a 2.5 cm thick sheathing laid parallel to the main beam. (c) The sheathing is supported on wooden battens, which are laid between the beams, at suitable intervals. (d) In order to reduce deflection, the battens may be propped at the middle of the span through joists. 	
3	 <i>Procedure</i> (a) Properly consolidate the floor by manually compacting the base to the required level and slope. (b) A 10 to 15 cm thick layer of lean cement concrete in the ratio of 1:6:12 or lime concrete should be laid over the entire area of the floor to be constructed. (c) A proper slope of 1:80 should be provided in the sub-grade (d) The slope should be checked with a straight edge at five to six places and any differences should be properly cured for seven days. (f) The bricks should be properly soaked in water for six hours. (g) Cement sand mortar or lime mortar of the required proportion should be prepared. (h) The bricks should be filled with mortar. The thickness of the joints should not exceed 1.0 cm. (j) The flooring should be cured for a minimum of seven days Or Following is the procedure to lay tiles on the floor. 1. Establish a datum level for the finished floor. 2. Tiles must be correctly positioned when they are placed and laid with joints. 3. Control the overall level of the finished floor by means of a spot check of levels. 4. Check whether the width of the joints is specified before setting out or use a tile spacer for uniform width spacing. 5. Provide 1% slope going to the floor drain. 6. Set out the tiling width joints of consistent width, 	5

		1
	ensuring they are horizontal and parallel.	
	7. Grouting of the joints should be carried out within	
	four hours of the completion of the laying of the	
	tiles so that the grout attaches itself firmly to the	
	bedding. Avoid disturbing the tiles during grouting.	
	8. Ensure that the joints are continuous from one	
	surface to the next where adjoining tile surfaces are	
	in different planes.	
4	(a) Properly consolidate the floor by manually	3
	compacting the base to the required level and slope.	
	(b) A 10 to 15 cm thick layer of lean cement concrete in	
	the ratio of 1:6:12 or lime concrete should be laid	
	over the entire area of the floor to be constructed.	
	(c) A proper slope of 1:80 should be provided in the	
	sub-grade	
5	Scaffolding is a temporary structure on the outside of a	3
	building, made of wooden planks and metal poles, used	
	by workmen while building construction, repairing, or	
	cleaning the building The material used for	
	scaffolding is tubes, bamboos, couplers and boards.	
6	Single scaffolding is generally used for brick masonry. It is also called	3
0	bricklayer's scaffolding Single scaffolding consists of standards, ledgers,	5
	putlogs, etc. It is parallel to the wall at a distance of	
	about 1.2 m.	
	• The distance between the standards	
	is about 2 to 2.5 m. Ledgers connect	
	the standards at a vertical interval	
	of 1.2 to 1.5 m.	
7		3
/	In cement lime mortar, a portion of the cement is	5
	replaced by hydrated lime. It spreads more easily under	
	the trowel and produces a more elastic material. In lime	
	cement mortar a portion of lime is replaced by cement.	
	It makes the mortar stronger, more smoother and	
-	workable and also the mortar sets earlier.	
8	English Bond consists of an alternate course of	3
	headers and stretchers . Queen closer, that	
	is, half of the brick cut lengthwise, shall be introduced	
	after the first header to break the vertical joint.	
	• Flemish Bond is an arrangement of bonding	
	brickwork. Each course consists of alternate	
	headers and stretchers. The headers of each course	
	are centred over the stretcher in the course below.	
	For breaking of vertical joints in successive courses,	
	closers are inserted in alternate courses next to	
	quoin (a cornerstone) headers

	Trowel, Plumb Rule and Bob, Straight Edge, Mason's Square, Spirit Level, Steel Tape, Brick Hammer also write short note on above	
9	In construction, rubble masonry stones of irregular sizes are used. The stones as obtained from the quarry are used as they are or are broken and shaped to suitable sizes by means of a hammer as the work progresses. The strength of rubble masonry depends upon the following three factors: (i) The quality of mortar (ii) The use of long through stones at frequent intervals (iii) The proper filling of mortar in the space between Stones Or This is a superior quality of masonry and is built from accurately dressed stones with uniform and very finejoints (Fig. 1.14). The various types of Ashlar masonry can be classified under the following categories. • Ashlar fine • Ashlar rough-tooled • Ashlar rock quarry-faced • Ashlar chamfered • Ashlar facing	3
10	Ashlar block in course In concrete construction, the false work supports the shuttering moulds. Temporary Timber, plywood, metal or other material is used to provide support to wet concrete mix till it gets strength for self support in formwork. The formwork	2
	also produces the desired finish on concrete surface. Shuttering or formwork should be strong enough to support the weight of wet concrete mix and also the pressure of concrete inside or on top of the formwork	
11	 A good formwork should satisfy the following requirements. (a) The material for formwork should be cheap and can be reused many times. (b) It should be waterproof and should not absorb water from the concrete. There should be minimum shrinkage and swelling. (c) It should be strong enough to bear all loads – dead load of concrete, live load of labour during pouring, compaction and curing. (d) It should be hard so that there is minimum deflection. 	2

10		
12	(a) study and find good jobs to take care of ourselves	2
	and our families.	
	(b) work hard and contribute to society.	
	(c) learn and develop skills so that we get add value	
10	in our community	2
13	Fulfil Customer Needs	2
	Demand means a product or service that people want.	
	Entrepreneurs find out what people want. Then, they	
	use their creativity to come up with a business idea that	
	will meet that demand.	
	Use Local Materials	
	Entrepreneurs use the material and people available	
	around them, to make products at low cost.	
14	Steel scaffolding is constructed by steel tubes, which are fixed together	2
	by steel couplers or fittings.	
	• It is very easy to construct or dismantle.	
	• It has great strength, durability and high fire resistance.	
	• It is not economical but is safer for workers. It is used extensively.	
	Or	
	The different hand tools used for erecting or dismantling	
	scaffolds are as follows.	
	• Hammer: delivers a blow (a sudden impact) to an	
	object. Most hammers are hand tools used to drive	
	nails, fit parts, forge metal, and break apart objects	
	• Spanner: is used to provide grip and mechanical	
	advantage in applying torque to turn objects – usually	
	rotary fasteners, such as nuts and bolts – or to keep	
	them from turning	
	• Pulley: is a wheel with a grooved rim around which	
	a cord passes that helps to change the direction of	
	force applied to the cord. A pulley is used to raise	
	heavy weights	
15	In construction, rubble masonry stones of irregular sizes	2
10	are used. The stones as obtained from the quarry are	-
	used as they are or are broken and shaped to suitable	
	sizes by means of a hammer as the work progresses. The	
	strength of rubble masonry depends upon the following	
	three factors:	
	(i) The quality of mortar	
	(ii) The use of long through stones at frequent intervals	
	(iii) The proper filling of mortar in the space between	
	Stones	
	Rubble masonry is further classified into the following	
	categories.	
	Coursed rubble	
	• Uncoursed rubble	

	• Random rubble	
	• Dry rubble	
	Polygonal rubble	
	• Flint rubble	
	Or
